# GOLF CLUB HEAD HAVING AN INSERT CAVITY REAR APERTURE

## BACKGROUND OF THE INVENTION

This invention relates generally to golf equipment and, in particular, to a golf club head having a cavity for receiving a face insert.

5 United States Patent No. 6,238,302 to Helmstetter, et al. ("the '302 patent") discloses a golf club head with a polymer face insert. The face insert is disposed in a cavity formed in the club head face. The insert has a plurality of tabs formed on its perimeter edge that engage the walls of the cavity to center the insert in the cavity. The insert is installed by bonding it to the club head using an adhesive disposed in the cavity. During assembly, as the insert is placed in the cavity, the tabs permit  
10 air and any excess adhesive to escape the cavity through the gaps between the tabs, thereby promoting a good structural bond between the insert and the golf club head. Any excess adhesive that flows out of the cavity can simply be removed by wiping the surface of the insert before the adhesive cures. One drawback of the golf club head disclosed in the '302 patent is that the delicate features of tabs on the polymer insert are difficult to form by conventional processes other than expensive laser cutting.

15

## SUMMARY OF THE INVENTION

The present invention comprises a golf club head including a body having a front face with a cavity formed therein. The cavity is defined by a bottom wall and a side wall, and has at least one aperture passing through the bottom wall to the rear surface of the club head body. A face insert is  
20 mounted in the cavity. In an illustrative embodiment of the present invention, the face insert is mounted by applying an adhesive layer between the face insert and the cavity. As the face insert is pressed into the cavity, air and any excess adhesive escapes through the cavity aperture to the rear surface of the club where it can easily be removed, for example by wiping with solvent. The insert

itself may be formed with a continuous lip extending outward from the perimeter surface of the face insert. The lip is sized and shaped to form a close-tolerance fit with the side wall of the cavity. The close fit ensures that no liquid adhesive escapes to the front side of the cavity to mar the club face. The face insert may be solid, or may include a rearward facing cavity containing a second insert made of a different material. The apertures in the back of the cavity may be of regular cross-section, or may be in the form of letters of the alphabet, for example, to spell out the manufacturer's name for aesthetic purposes.

#### BRIEF DESCRIPTION OF THE DRAWING

The present invention will be better understood from a reading of the following detailed description, taken in conjunction with the accompanying drawing figures in which like references designate like elements, and in which:

FIG. 1 is a front exploded perspective view of a golf club head including features of the present invention;

FIG. 2 is a rear exploded perspective view of the golf club head of FIG. 1;

FIG. 3 is a front elevational view of the golf club head shown in FIG. 1;

FIG. 4 is a sectional view taken along lines 4-4 of FIG. 3;

FIG. 5 is an enlarged sectional view similar to FIG. 4 showing an alternative embodiment;

FIG. 6 is a rear exploded perspective view of an alternative embodiment of a golf club head incorporating features of the present invention; and

FIG. 7 is a rear exploded perspective view of yet another alternative embodiment of a golf club head incorporating features of the present invention.

## DETAILED DESCRIPTION

With reference to FIGs. 1 and 2, a golf club head 10, preferably a golf putter head, comprises a body 12 and a hosel 14 with a boss 16, counterbored for receiving one end of a golf club shaft (not shown). The body 12 has a front face 18, a heel end 20 and a toe end 22. The front  
5 face 18 has a first cavity 24 formed therein defined by a bottom wall 26 and side wall 28. The first cavity 24 has a first aperture 30 and a second aperture 32 passing from first cavity 24 through bottom wall 26 to rear surface 34 of body 12.

The body 12, including the first cavity 24, is typically formed by an investment casting process. The bottom wall 26 and side wall 28 along with apertures 30 and 32 are then shaped by a  
10 milling process to maintain precise tolerances. A first insert hereinafter referred to as a face insert 36 is disposed in the first cavity 24. The body 12 is preferably made of a suitable metal such as steel, and the face insert 36 is preferably made of a polymer, more preferably an elastomeric polymer such as polyurethane. In the illustrative embodiment, the face insert 36 is made of a polyurethane manufactured by BASF under the trademark ELASTOLLAN which is an elastomeric  
15 polyurethane having a density of 1.14 grams per cubic centimeter and a Shore A hardness of 98. Optionally, face insert 36 has a second cavity 38 formed therein which is defined by a bottom surface 40 and a side surface 42.

A second insert hereinafter referred to as a back cavity insert 44 is disposed in the second cavity 38. Back cavity insert 44 is preferably formed of a polymer having a hardness (durometer)  
20 and/or resiliency that is different from that of the face insert 36. In the illustrative embodiment, the back cavity insert 44 is made of a silicone dielectric gel, silicone rubber, or other highly resilient elastomer. The face insert 36 is formed by an injection molding process with a maximum width "W" of approximately 2.300 inches and a maximum height "H" of approximately 0.725 inch. The

face insert 36 also has a thickness "T" of approximately 0.200 inch measured between the front surface 46 and back surface 48. The first cavity 24 has a depth of approximately 0.215 inch as measured between the front face 18 and the cavity bottom wall 26. The second cavity has a depth of approximately 0.100 inch measured between the back surface 48 and the bottom surface 40 of second cavity 38.

Face insert 36 further includes a continuous lip 50 extending outward from perimeter edge 52 of face insert 36. Lip 50 is sized and shaped to form a close-tolerance fit with the side wall 28 of the first cavity 24 for reasons that are more fully explained hereinafter. Back cavity insert 44 may be cured in place within second cavity 38 or may be separately molded and attached by conventional means (e.g., adhesive) within second cavity 38.

With reference to FIG. 4, according to one embodiment, back cavity insert 44 itself comprises an elastomeric adhesive. The club head 10 is assembled by filling second cavity 38 with the uncured elastomeric adhesive and inserting the face insert into first cavity 24. As face insert 36 is pressed into first cavity 24, excess adhesive and air that would otherwise be trapped within first cavity 24 escapes through first and second apertures 30 and 32 allowing face insert 36 to seat fully against bottom wall 26 of first cavity 24.

Alternatively, as shown in FIG. 5, back cavity insert 44 is cured in place or attached by conventional means such as an adhesive layer within second cavity 38. Face insert 36 is thereafter attached to body 10 by adhesive means such as a liquid adhesive as described above or by using double sided tape 56, preferably a double coated acrylic foam or adhesive transfer film manufactured by 3M Company that is disposed between back cavity insert 44 and bottom wall 26 of first cavity 24. In the illustrative embodiment of FIG. 5, double sided adhesive tape 56 is applied to exposed surface 58 of back cavity insert 44 before face insert 36 is installed in body 12. Double

sided adhesive tape 56 is approximately 0.015 inch thick and is cut to a size and shape that matches exposed surface 58. Double sided adhesive tape 56 may be cut so that one or the other of face insert 36 or back cavity insert 44 is exposed directly to apertures 30 and 32 for aesthetic reasons so that the back side of the insert 36 or 44 may be seen through the apertures 30, 32.

5           As shown in FIG. 6, according to an alternative embodiment of a golf club head 10a incorporating features of the present invention, apertures 60, 62, 64 and 66 may be formed with cross-sections in the shape of letters of the alphabet, for example spelling out the manufacture's name for aesthetic purposes. Alternatively, as shown in the golf club head 10b of FIG. 7, apertures 70 and 72 are placed proximal heel end 20 and toe end 22, respectively. This arrangement of  
10   apertures 70, 72 permits face insert 36 to be installed and thereafter an adhesive is injected through one of apertures 70 and 72 until it flows out of the other of apertures 70 and 72. This process eliminates the need for using transfer adhesives or tapes while at the same time facilitating use of automated equipment for applying the adhesive.

          Although certain illustrative embodiments and methods have been disclosed herein, it will be  
15   apparent from the foregoing disclosure to those skilled in the art that variations and modifications of such embodiments and methods may be made without departing from the spirit and scope of the invention. Accordingly, it is intended that the invention should be limited only to extent required by the appended claims and the rules and principals of applicable law.
